Solutions to HW 9

```
library(MASS)
library(leaps)
data<-birthwt</pre>
```

1)

a)

The following variables are categorical:

- low (binary)
- race
- smoke (binary)
- ht (binary)
- ui (binary)

Note that the binary variables are 0-1 dummy coded, so we don't have to convert them to factors. Race needs to be converted to a factor:

```
##convert the race variable in the dataframe
data$race<-factor(data$race)

##give more descriptive labels to levels
levels(data$race)<-c("W", "B", "O")</pre>
```

b)

I agree with my classmate since low is a binary version of response variable, so it is directly based on the response variable.

c)

i)

```
##perform all possible regressions (1st order)
allreg <- regsubsets(bwt ~age+lwt+race+smoke+ptl+ht+ui+ftv, data=data, nbest=1)</pre>
```

```
##best adj r2

```

The regression equation from backward elimination is

$$\hat{y} = 2837.26 + 4.24 lwt - 475.06 I_1 - 348.15 I_2 - 356.32 smoke - 585.19 ht - 525.52 ui$$

2)

\mathbf{a}

Based on forward selection, the model selected had price, discount, and promo as the predictors.

b)

- 1. The algorithm starts out with a model with none of the five predictors in the model.
- 2. The algorithm then considers adding one of the predictors into the model. For each predictor added, the algorithm calculates the AIC, which measures the model in terms of fit and complexity. A small value for the AIC is desirable.
- 3. The algorithm selects the predictor, which, after adding to the model, results in the following two situations: (i) results in the smallest AIC and (ii) reduces the AIC when compared to the previous model, which in this case is the model with none of the predictors. In this dataset, adding the predictor discount accomplishes both of these criteria. Once a predictor is added to the model, it is never removed in forward selection.
- 4. The algorithm repeats steps 2. and 3., by considering adding a predictor to the model with discount in it.
- 5. The algorithm stops when criteria (ii) in step 3. cannot be fulfilled by adding any of the remaining predictors.

c)

Some pieces of advice:

• All possible regression only consider first order models. Need consultation with subject matter expert if models of higher order should be considered.

- Need to check with original purpose of study. Is there a specific predictor that has to be evaluated. Will this model answer the questions of interest?
- Automated search procedures should not be viewed as the end of the model building process. In fact, using other search procedures or with different starting points may yield in a different model.
- We need to verify the regression assumptions are met by examining diagnostic plots.

3)

Advantage of \mathbb{R}^2 : has a nice geometrical interpretation. \mathbb{R}^2 measures the proportion of the variance in the response variable that can be explained by our model. The adjusted \mathbb{R}^2 does not have this interpretation.

Advantage of adjusted R^2 : the addition of predictors that do not help further explain the response variable will lead to a decrease in adjusted R^2 . On the other hand, R^2 always increases, regardless of whether the predictor helps further explain the variance in the response variable or not. So R^2 will always pick a larger model, while adjusted R^2 balances between model fit and simplicity.

4)

```
PRESS <- function(linear.model) {
    ## calculate the predictive residuals
    pr <- residuals(linear.model)/(1-lm.influence(linear.model)$hat)
    ## calculate the PRESS
    PRESS <- sum(pr^2)
    return(PRESS)
}</pre>
```
